The Department of Health acknowledges the providers of the many sources of data used in this report and greatly appreciates their contribution.

**SUMMARY**

- Across all jurisdictions, seasonal influenza activity has continued to decline following recent peaks in activity. In South Australia, where activity has plateaued for several weeks, there has been a decline in the most recent week.
- As at 26 September 2014, there have been 59,867 cases of laboratory confirmed influenza reported, with 5,900 notifications occurring during the report fortnight.
- Nationally influenza A is the predominant influenza virus type. Influenza A(H1N1)pdm09 continues to be the dominant circulating virus subtype in the Northern Territory, South Australia, Tasmania and Victoria while in New South Wales and the Australian Capital Territory, influenza A(H3N2) is the most common virus type. The proportion of influenza A(H3N2) has increased in recent weeks in Queensland and Western Australia where both strains now co-circulate in similar proportions. The usual, late season increase in influenza B infections has also been noted in recent weeks.
- The influenza vaccine is likely to provide good coverage against the currently circulating viruses.
- The number of influenza associated hospitalisations to sentinel sites has declined over the past fortnight, with around 10% of cases admitted directly to ICU. The majority of hospital admissions have been associated influenza A infections and the median age of cases is 51 years.
- The severity of the 2014 influenza season appears to be moderate across most jurisdictions. However, more severe activity was noted in NSW, where influenza A(H3N2) circulated at higher levels and affected people in older age-groups, which has led to a substantial number of outbreaks in aged care facilities.
- The WHO released its recommendations for the composition of the 2015 southern hemisphere influenza season vaccine which includes changes to the A(H3N2) and B vaccine strains.

Figure 1. Notifications of laboratory confirmed influenza, Australia, 1 January 2009 to 26 September 2014, by week.

---

1 ACT reports influenza A subtypes as A(H3). Based on national subtyping and characterisation data, these cases are assumed to be A(H3N2).
KEY INDICATORS

Influenza activity and severity in the community is monitored using the following indicators and surveillance systems:

<table>
<thead>
<tr>
<th>Is the situation changing?</th>
<th>Indicated by trends in:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>laboratory confirmed cases reported to the National Notifiable Diseases Surveillance System (NNDSS);</td>
</tr>
<tr>
<td></td>
<td>influenza associated hospitalisations;</td>
</tr>

1. Geographic Spread of Influenza Activity in Australia

In the fortnight ending 26 September 2014, influenza activity was stable or declining in all regions except the Top End region of the Northern Territory (NT). No report was available from the Australian Capital Territory (ACT). The geographic spread of influenza activity reported by state and territory health departments was ‘widespread’ in New South Wales (NSW), the NT, SA, and Tasmania (Tas) and the metropolitan Perth area of Western Australia (WA). ‘Regional’ activity was reported in central and southern Queensland (Qld), the Pilbara/Kimberley and the country-south regions of WA and Victoria (Vic). Tropical north Qld continues to recorded sporadic activity. ILI activity monitored through syndromic surveillance systems was reported as increased in the Top End region of the NT.

Figure 2. Map of influenza activity by state and territory, 13 September to 26 September 2014.
2. Influenza-like Illness Activity

Community Level Surveillance

FluTracking

FluTracking, a national online system for collecting data on ILI in the community, indicated that in the week ending 28 September 2014, fever and cough continued to decrease and was reported by 2.2% of vaccinated participants and 2.3% of unvaccinated participants. Similarly, rates of fever, cough and absence from normal duties reduced during the period and was reported by 1.2% of vaccinated participants and 1.6% of unvaccinated participants. Rates of fever and cough among participants this year have peaked close to the peak rate observed in 2012. Currently activity has returned to levels that are within the range for this time of year (figure 3). In the week ending 28 September 2014, 60% of participants reported having received the 2014 influenza vaccine which is similar to the corresponding period in 2013.

Figure 3. Proportion of fever and cough among FluTracking participants, between May and October, 2010 to 2014, by week.

National Health Call Centre Network

ILI related calls to the National Health Call Centre Network (NHCCN) reached an apparent seasonal peak during the week ending 24 August, and have continued to decrease sharply in recent weeks. The proportion of ILI related calls to the NHCCN is within the range observed in recent years (figure 4).

Figure 4. Number of calls to the NHCCN related to ILI and percentage of total calls, Australia, 1 January 2010 to 28 September 2014, by week.

Note: NHCCN data do not include Queensland and Victoria
Source: NHCCN
Sentinel General Practice Surveillance

In the fortnight ending 28 September 2014, the sentinel general practitioner ILI consultation rate decreased markedly. The rate of ILI consultations had a sustained peak during August, which was similar to the peak levels observed in 2012. Currently, the rate of ILI consultations is within the range observed at a similar period in recent years (figure 5).

Figure 5. Weekly rate of ILI reported from GP ILI surveillance systems*, 1 January 2010 to 28 September 2014, by week.

In the fortnight ending 28 September 2014, specimens were collected from around 45% of Australian Sentinel Practices Research Network (ASPREN) general practitioner ILI patients. Of these patients, 23% were positive for influenza, compared with 30% in the previous fortnight. Influenza A(H1N1)pdm09 viruses are the predominant subtype (figure 6 and table 1). The proportion of ILI patients positive for other respiratory viruses increased slightly to 20%, with human metapneumovirus detected most commonly.

Table 1. ASPREN laboratory respiratory viral test results of ILI consultations, 1 January to 28 September 2014.

* Other respiratory viruses include human metapneumovirus, RSV, parainfluenza, adenovirus and rhinovirus.
Figure 6. Proportion of respiratory viral tests positive for influenza in ASPREN ILI patients and ASPREN ILI consultation rate, 1 January to 28 September 2014, by week*.

SOURCE: ASPREN and WA SPN

*No ILI or consultation data were available from the NT for this reporting period.

Sentinel Emergency Department Surveillance

Western Australia Emergency Departments

The rate of viral respiratory presentations to WA emergency departments was stable during the last fortnight following an apparent peak period between mid-July and late August. The current presentation rates are within the range reported in recent seasons (figure 7).

Figure 7. Number of respiratory viral presentations to Western Australia emergency departments, 1 January 2010 to 28 September 2014, by week.

Source: WA Department of Health
New South Wales Emergency Departments

In the week ending 21 September 2014, the number and proportion of ILI presentations to NSW emergency departments was stable at moderate levels (figure 8). ILI and pneumonia admissions to critical care wards decreased slightly this week but remained at the upper end of the usual range for this time of year.

The NSW emergency department surveillance system uses a statistic called the ‘index of increase’ to indicate when ILI presentations are increasing at a statistically significant rate. An index value greater than 15 suggests that influenza is circulating widely in the NSW community. The index crossed the season threshold of 15 on 1 July 2014, and peaked at 50.7 in the week ending 13 August 2014. Currently this index is 11.3, which is below the seasonal threshold.

Northern Territory Emergency Departments

The rate of ILI presentations to NT emergency departments peaked at 134 ILI cases per 1,000 ED presentations in the week ending 6 September and in the most recent week continued to decrease to 85 ILI cases per 1,000 ED presentations. The rate of ILI presentations since July have been similar to the trend observed in 2011 (figure 9).
3. Laboratory Confirmed Influenza Activity

Notifications of Influenza to Health Departments

For the year to date to 26 September, there were 59,867 laboratory confirmed notifications of influenza: 19,381 in NSW; 15,998 in Qld; 9,161 in SA; 8,431 in Vic; 4,467 in WA; 1,129 in the ACT; 695 in the NT and 605 in Tas. The 2014 seasonal rise in notifications appears to have started in mid-June 2014 and peaked during the week ending 22 August 2014.

In the fortnight ending 26 September 2014 there were 5,900 notifications reported to the NNDSS (figure 10). SA (1,736), Qld (1,472) and NSW (1,089), and together contributed over three-quarters (73%) of notifications this fortnight, followed by Vic (947), WA (420), ACT (106), NT (72) and Tas (58). A weekly breakdown of notification trends by jurisdiction shows that influenza notifications may have been declining in almost all jurisdictions. In SA, where activity had been plateauing for several weeks, there has been a sharp decline in the most recent week (figure 11).
Figure 10. Notifications of laboratory confirmed influenza, Australia, 1 January to 26 September 2014, by state or territory and week.

Figure 11. Notifications of laboratory confirmed influenza, 1 January to 26 September 2014, by state or territory and week.
So far in 2014, notifications have been highest among those aged less than 5 years with a secondary peak in those aged between 30 and 44 years (figure 12). This age distribution trend is consistent with previous years dominated by influenza A(H1N1)pdm09, in which there were very few notifications in older age groups. In contrast, influenza seasons not dominated by influenza A(H1N1)pdm09, have an age distribution that is typically characterised by high rates of influenza in the elderly and in children aged less than 5 years. The increase in older age groups in 2014 has mostly been associated with influenza A(H3N2) activity.

**Figure 12. Notifications of laboratory confirmed influenza, 1 January to 26 September 2014, by subtype* and age group.**

Of the 5,900 influenza notifications reported to the NNDSS this reporting period, 84% were influenza A (74% A(unsubtyped), 4% A(H1N1)pdm09 and 5% A(H3N2)), 15% were influenza B and <1% were untyped or influenza A&B co-infections (figure 13).

The distribution of the two main virus types, influenza A and influenza B, has been variable between jurisdictions. Influenza A(H3N2) continues to dominate in NSW and the ACT*, whereas influenza A(H1N1)pdm09 is dominant in the NT, SA, Tas and Vic. In recent weeks, the proportion of A(H3N2) has increased in Qld and WA where both A subtypes currently co-circulate in similar proportions. The typical, late season increase in influenza B infections has also been noted in recent weeks.

For the calendar year to 26 September 2014, 89% of cases were reported as influenza A (70% A(unsubtyped), 4.4% A(H1N1)pdm09 and 5.3% A(H3N2)) and 15% were influenza B. Less than 1% were reported as either influenza A&B co-infections, influenza type C or were untyped (figure 13).

---

* These subtyped ACT influenza cases have been reported as A(H3). Based on nationally available subtyping and characterisation data, these cases are assumed to be A(H3N2).
Figure 13. Notifications of laboratory confirmed influenza, Australia, 1 January to 26 September 2014, by sub-type* and week.

Source: NNDSS

Sentinel Laboratory Surveillance

Results from sentinel laboratory surveillance systems for this reporting period show that approximately 17% of the respiratory viral tests conducted over this period were positive for influenza (table 2). Influenza A was the most common type, with the proportion of A(H1N1)pdm09 and A(H3N2) similar in WA and Tas (figure 14). Influenza was the most commonly detected respiratory virus overall. Influenza virus subtyping data was not available for NSW for this reporting period. No data were available from the Victorian NIC for this period.

**Hospitalisations**

**Influenza Complications Alert Network (FluCAN)**

In the last fortnight, the Influenza Complications Alert Network (FluCAN) sentinel hospital surveillance system reported 230 admissions with confirmed influenza. Since 7 April 2014, 10% of influenza patients have been admitted directly to ICU and the majority of overall influenza admissions have been with influenza A (76%) (figure 15). Around 43% of the cases are aged between 16 and less than 65 years (median age 51 years) and 73% of all cases had known medical co-morbidities reported.

**Figure 15. Number of influenza hospitalisations at sentinel hospitals, 7 April to 26 September 2014, by week and influenza subtype.**

Source: FluCAN Sentinel Hospitals
Queensland Public Hospital Admissions (EpiLog)

Admissions to public hospitals in Queensland with confirmed influenza are detected through the EpiLog system. Up to 28 September 2014, there were 2,028 admissions, including 251 to intensive care units (figure 16). The majority of hospital admissions have been associated with influenza A infections, and of those infections that have been subtyped, these have mostly been A(H1N1)pdm09. In the year to date, the age distribution of influenza-associated hospitalisations shows a peak in the 0-9 years age group, especially among those aged 1-4 years, and the 60-69 years age group. The median age of hospitalised cases is 51 years with a range of less than one to 97 years.

Figure 16. Number of influenza admissions to Queensland public hospitals, with onset from 1 January to 28 September 2014, by week and type of admission.

Paediatric Severe Complications of Influenza

The Australian Paediatric Surveillance Unit conducts seasonal surveillance between July and October annually of children aged 15 years and under who are hospitalised with severe complications of influenza. Between 1 July 2014 and 30 September 2014, there have been 71 hospitalisations associated with severe complications of influenza reported, with 19 of these cases in the most recent fortnight. The median age of these cases was 3 years. Almost all (97%) of cases were associated with influenza A infections, including one influenza A&B co-infection; 32% admitted to ICU; and 31% were reported as having underlying chronic conditions.

Deaths Associated with Influenza and Pneumonia

Nationally Notified Influenza Associated Deaths

So far in 2014, 57 influenza associated deaths have been notified to the NNDSS, with a median age of 69 years (range 5 to 96 years). Influenza type A infection was reported in all of the influenza associated deaths. The number of influenza associated deaths reported to the NNDSS is reliant on the follow up of cases to determine the outcome of their infection and most likely does not represent the true mortality impact associated with this disease.

New South Wales Influenza and Pneumonia Death Registrations

Please note, updated influenza and pneumonia death registration data have not been available since early June 2014.

Death registration data for the week ending 6 June 2014 show that there were 1.02 pneumonia or influenza associated deaths per 100,000 population in NSW, which is below the epidemic threshold of 1.45 per 100,000
NSW population (figure 17). Up to 6 June 2014, out of 21,199 deaths in NSW, five death certificates noted influenza and 1,866 noted pneumonia. The majority of the death certificates mentioning influenza were in elderly people.

Figure 17. Rate of deaths classified as influenza and pneumonia from the NSW Registered Death Certificates, 1 January 2009 to 6 June 2014.

4. Virological Surveillance

Typing and Antigenic Characterisation

WHO Collaborating Centre for Reference & Research on Influenza (WHO CC), Melbourne

From 1 January to 2 October 2014 there were 1,329 Australian influenza viruses subtyped by the WHO CC, with 71% being A(H1N1)pdm09, 19% influenza A(H3N2) and 10% influenza B. The majority of influenza B viruses were from the B/Yamagata lineage (table 3).

</tbody>
</table>

Note: Viruses tested by the WHO CC are not necessarily a random sample of all those in the community.
State indicates the location the sample originated from, not the submitting laboratory.
There may be up to a month delay on reporting of samples.

Antiviral Resistance

The WHO CC has reported that from 1 January to 2 October 2014, one influenza virus (out of 1,187 tested) has shown reduced sensitivity to the neuraminidase inhibitor oseltamivir by enzyme inhibition assay. This virus was a A(H1N1)pdm09 virus.

2015 Southern Hemisphere Vaccine

In September 2014, the WHO recommended changes to the A(H3N2) and B viruses used in the 2015 southern hemisphere trivalent vaccine formulation. The recommended formulation is:

- A (H1N1): an A/California/7/2009 (H1N1) - like virus
- A (H3N2): an A/Switzerland/9715293/2013 (H3N2) - like virus
- B: a B/Phuket/3073/2013 - like virus
Further, the WHO continued to recommend that quadrivalent vaccines include an additional influenza B virus (B/Brisbane/60/2008-like virus) intended to provide vaccine coverage for both influenza B lineages.

The Australian Influenza Vaccine Committee will meet on Thursday 9 October to provide advice to the Therapeutic Goods Administration (TGA) on the composition of the 2015 seasonal influenza vaccine to be used in Australia.

### 5. International Influenza Surveillance

The WHO has reported that as at 22 September 2014, globally the influenza season is established in the southern hemisphere. Elsewhere influenza activity remained low except for some tropical countries in the Americas.

In eastern Asia, influenza activity remained low in most countries, with influenza A(H3N2) the main detected virus subtype. Influenza A(H3N2) and B activity continued in south China.

In New Zealand, through sentinel surveillance, the national ILI consultation rate has decreased markedly from 61.7 in the week ending 14 September to 20.5 per 100,000 patient population for the week ending 14 September 2014, which is below the seasonal threshold. Virological surveillance through both sentinel and non-sentinel laboratories shows that for the year to date, 90% have been influenza type A viruses. Of the influenza A viruses, 66% were A(H1N1)pdm09, 17% were A(H3N2) and the remainder were A(unsubtyped). Of the influenza B viruses, 32% were identified as B/Wisconsin/1/2010-like viruses (B/Yamagata lineage), 1.1% were B/Brisbane/6/2008-like viruses (B/Victoria lineage), and the remainder were not antigenically typed.

National Influenza Centres and other national influenza laboratories from 50 countries, areas or territories reported that for the period 24 August 2014 to 6 September 2014, a total of 2,675 specimens were positive for influenza viruses with 81% being influenza A and 19% influenza B. Of the sub-typed influenza A viruses, 30.1% were influenza A(H1N1)pdm09 and 69.9% were influenza A(H3N2). Of the characterised B viruses, 99% belong to the B/Yamagata lineage and 1% to the B/Victoria lineage.

**Human infection caused by the avian influenza A (H7N9) virus - China**

On 31 March 2013, the Chinese Government notified the WHO of human infections with avian influenza A(H7N9). This was the first time that H7N9 had been identified in humans. Up to 2 September 2014, there have been 452 laboratory-confirmed human cases with avian influenza A(H7N9) virus reported to the WHO. Of these cases, 38% have been fatal. All of the cases have been acquired in China, with 15 cases exported to Taiwan, Hong Kong and Malaysia.

Human infection appears to be associated with exposure to infected live poultry or contaminated environments, including markets where live poultry are sold. Current evidence suggests that this virus does not transmit easily from human to human, and does not support sustained human-to-human transmission.

### 6. State and Territory Surveillance Reports

For further information regarding current influenza activity at the jurisdictional level, please refer to the following State and Territory departments of health surveillance reports:

**New South Wales:** [Influenza Surveillance Report](http://www.health.nsw.gov.au/Infectious/Influenza/Pages/reports.aspx)

**South Australia:** [Weekly Epidemiological Summary (Influenza section)](http://www.sahealth.sa.gov.au/SurveillanceNotifiableConditions)

**Tasmania:** [fluTAS](http://www.dhhs.tas.gov.au/peh/communicable_diseases_prevention_unit)

**Victoria:** [VIDRL Influenza Surveillance Reports](http://www.vidrl.org.au/surveillance/influenza-surveillance)

7. Data Considerations

The information in this report is reliant on the surveillance sources available to the Department of Health. As access to sources increase as the season progresses, this report will include additional information.

This report aims to increase awareness of influenza activity in Australia by providing an analysis of the various surveillance data sources throughout Australia. While every care has been taken in preparing this report, the Commonwealth does not accept liability for any injury or loss or damage arising from the use of, or reliance upon, the content of the report. Delays in the reporting of data may cause data to change retrospectively. For further details about information contained in this report please contact the Influenza Surveillance Team (flu@health.gov.au).

Geographic Spread of Influenza Activity

<table>
<thead>
<tr>
<th>Activity level</th>
<th>Laboratory notifications</th>
<th>Influenza outbreaks</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sporadic</td>
<td>Small numbers of lab confirmed influenza detections, not above expected background level.</td>
<td>AND No outbreaks.</td>
</tr>
<tr>
<td>Localised</td>
<td>Lab confirmed influenza detections above background level in less than 50% of the influenza surveillance regions within the jurisdiction or area.</td>
<td>OR Single outbreak only.</td>
</tr>
<tr>
<td>Regional</td>
<td>Significant numbers of lab confirmed influenza detections above background level in less than 50% of the influenza surveillance regions within the jurisdiction or area.</td>

</tr>
</tbody>
</table>

+ Expected background level - defined by jurisdictional epidemiologists; represents the expected low level influenza activity that occurs outside of jurisdictional seasonal activity and is the baseline against which comparisons of change can be based.

++ Above background level - above the expected background level threshold as defined by jurisdictional epidemiologists.

* Influenza surveillance region within the jurisdiction/area as defined by jurisdictional epidemiologists.

+++ Significant numbers - a second threshold to be determined by the jurisdictional epidemiologists to indicate the level is significantly above the expected background level.

** Areas to be subdivisions of the NT (2 regions), WA (3 regions) and QLD (3 regions) that reflect significant climatic differences within those jurisdictions that result in differences in the timing of seasonal flu activity on a regular basis.

Change in activity level

The change in influenza activity level is based on a comparison of the activity level identified in the current reporting period with the previous period.

Syndromic Surveillance Activity

<table>
<thead>
<tr>
<th>Syndromic surveillance systems*</th>
</tr>
</thead>
<tbody>
<tr>
<td>No evidence of increase in ILI via syndromic surveillance systems</td>
</tr>
<tr>
<td>Evidence of increase in ILI via syndromic surveillance systems</td>
</tr>
</tbody>
</table>

* Syndromic surveillance systems include GP ILI sentinel surveillance, ED ILI surveillance and Flu tracking. The activity indicated by ILI based syndromic surveillance systems may be due to a variety of respiratory viruses. Therefore the report should indicate if other evidence suggests that the increase is suspected to be influenza activity or due to another respiratory pathogen. Syndromic surveillance is reported on a jurisdiction wide basis only.

FluTracking

FluTracking is a project of the University of Newcastle, the Hunter New England Area Health Service and the Hunter Medical Research Institute. FluTracking is an online health surveillance system to detect epidemics of influenza. It involves participants from around Australia completing a simple online weekly survey, which collects data on the rate of ILI symptoms in communities. For further information refer to the FluTracking website (www.flutracking.net/index.html).
National Health Call Centre Network

The National Health Call Centre Network (NHCCN) provides a nationally consistent approach for telephone based health advice to the community through registered nurses and is supported by electronic decision support algorithms. Data collected through the NHCCN is provided to the Department to enable monitoring of the number and proportion of calls relating to predefined patient guidelines. These guidelines have been grouped to create an influenza-like illness syndrome to enable monitoring of community disease activity. These data currently do not include Queensland or Victoria. For further information refer to the Health Direct website (http://www.healthdirect.org.au).

Sentinel General Practice Surveillance

The sentinel general practice ILI surveillance data between 2009 and 2013 consists of two main general practitioner schemes, the Australian Sentinel Practices Research Network (ASPREN) and a Victorian Infectious Disease Reference Laboratory (VIDRL) coordinated sentinel GP ILI surveillance program. Additionally, between 2008 and 2009 a Northern Territory surveillance scheme also operated, however this scheme has since been incorporated in to the ASPREN scheme. The national case definition for ILI is presentation with fever, cough and fatigue.

The ASPREN currently has sentinel GPs who report ILI presentation rates in NSW, NT, SA, ACT, VIC, QLD, TAS and WA. The VIDRL scheme operates in metropolitan and rural general practice sentinel sites throughout Victoria and also incorporates ILI presentation data from the Melbourne Medical Deputising Service. As jurisdictions joined ASPREN at different times and the number of GPs reporting has changed over time, the representativeness of sentinel general practice ILI surveillance data in 2013 may be different from that of previous years.

ASPREN ILI surveillance data are provided to the Department on a weekly basis throughout the year, whereas data from the VIDRL coordinated sentinel GP ILI surveillance program is provided between May and October each year.

Approximately 30% of all ILI patients presenting to ASPREN sentinel GPs are swabbed for laboratory testing. Please note the results of ASPREN ILI laboratory respiratory viral tests now include Western Australia.

Further information on ASPREN is available at the ASPREN website (www.dmac.adelaide.edu.au/aspren) and information regarding the VIDRL coordinated sentinel GP ILI surveillance program is available at from the VIDRL website (www.victorianflusurveillance.com.au).

Sentinel Emergency Department Data

(i) Western Australia – Emergency Department ILI cases are determined from presentations coded as upper respiratory tract infection [J06.9] or viraemia [B34.9]), and are extracted from the Western Australian Emergency Department Information System (EDIS). These EDIS diagnostic codes were chosen as they best correlated with notification and laboratory detection data for influenza virus. The EDIS system incorporates ICD-10 clinical-coded presentation and admission data from the most significant public or public/private hospitals with emergency department services in the greater Perth metropolitan area (Royal Perth Hospital, Sir Charles Gairdner Hospital, Fremantle Hospital, Princess Margaret Hospital, King Edward Memorial Hospital, Armadale-Kelmscott Memorial Hospital, Joondalup Health Campus, Swan District Hospital and Rockingham General Hospital), plus Bunbury Regional Hospital from the Southwest city of Bunbury. For further information, please refer to the Western Australian Department of Health Virus WAtch website (www.public.health.wa.gov.au/3/487/3/virus_watch.pm).

(ii) New South Wales – Emergency Department ILI surveillance data are extracted from the ‘NSW Health Influenza Surveillance Report’. NSW Health Public Health Real-time Emergency Department Surveillance System (PHREDSS) managed by the Centre for Epidemiology and Evidence, NSW Ministry of Health. Data from 59 NSW emergency departments (ED) are included. Comparisons are made with data for the preceding five years. Recent counts are subject to change. For further information, please refer to the NSW Health Influenza Surveillance website (www.health.nsw.gov.au/Infectious/Influenza/Pages/reports.aspx).

(iii) Northern Territory – This syndromic surveillance system collects data from all the public hospitals in the Northern Territory: Royal Darwin, Gove District, Katherine District, Tennant Creek and Alice Springs. The definition of ILI is presentation to ED in the NT with one of the following presentations: febrile illness, cough, respiratory infection, or viral illness.

National Notifiable Diseases Surveillance System (NNDSS)

Laboratory confirmed influenza (all types) is notifiable under public health legislation in all jurisdictions in Australia. Confirmed cases of influenza are notified through the NNDSS by all jurisdictions. The national case definition is available from the Department of Health’s website (www.health.gov.au/internet/main/publishing.nsf/Content/cda-surveil-nndss-casedefs-cd_flu.htm). Analyses of Australian notifications are based on the diagnosis date, which is the earliest of the onset date, specimen date or notification date.
Sentinel Laboratory Surveillance data

Laboratory testing data are provided weekly directly from PathWest (WA), VIDRL (VIC), ICPMR (NSW), and Tasmanian public hospital laboratory PCR testing results. For Tasmania, the PCR results represent testing at a major Tasmanian public hospital laboratory, which also accepts referred specimens from all departments of emergency medicine and hospital inpatients from across the state.

Influenza Complications Alert Network (FluCAN)

The Influenza Complications Alert Network (FluCAN) sentinel hospital system monitors influenza hospitalisations at the following sites:

- Australian Capital Territory – the Canberra Hospital and Calvary Hospital;
- New South Wales – John Hunter Hospital, Westmead Hospital and Children’s Hospital at Westmead¹;
- Northern Territory – Alice Springs Hospital;
- Queensland – the Mater Hospital, Princess Alexandra Hospital and Cairns Base Hospital;
- South Australia – Royal Adelaide Hospital;
- Tasmania – Royal Hobart Hospital;
- Victoria – Geelong Hospital, Royal Melbourne Hospital, Monash Medical Centre and Alfred Hospital;
- Western Australia – Royal Perth Hospital and Princess Margaret Hospital¹.

¹=Paediatric hospital site

Influenza counts are based on active surveillance at each site for admissions with PCR-confirmed influenza in adults. Some adjustments may be made in previous periods as test results become available. ICU status is as determined at the time of admission and does not include patients subsequently transferred to ICU. Dates listed as date of admission except for patients where date of test is more than 7 days after admission. Admissions listed as influenza A includes untyped and seasonal strains and may include H1N1/09 strains if not typed.

Queensland Public Hospital Admissions (EpiLog)

EpiLog is a web based application developed by Queensland Health. This surveillance system generates admission records for confirmed influenza cases through interfaces with the inpatient information and public laboratory databases. Records are also able to be generated manually. Admissions data reported are based on date of reported onset. For further information refer to Qld Health’s Influenza Surveillance website (www.health.qld.gov.au/ph/cdb/sru_influenza.asp).

Deaths associated with influenza and pneumonia

Nationally reported influenza associated deaths are notified by jurisdictions to the NNDSS, which is maintained by the Department of Health. Notifications of influenza associated deaths are likely to underestimate the true number of influenza associated deaths occurring in the community.

WHO Collaborating Centre for Reference & Research on Influenza

Data on Australian influenza viruses are provided weekly to the Department from the WHO Collaborating Centre for Reference & Research on Influenza based in Melbourne, Australia.
