Weekly epidemiological report

COVID-19, Australia: Epidemiology Report 6:
Reporting week ending 1900 AEDT 7 March 2020

COVID-19 National Incident Room Surveillance Team

Summary

This is the sixth epidemiological report for coronavirus disease 2019 (COVID-19), reported in Australia as at 19:00 Australian Eastern Daylight Time [AEDT] 7 March 2020. It includes data on COVID-19 cases diagnosed in Australia, the international situation and a review of current evidence.

Keywords: SARS-CoV-2; novel coronavirus; 2019-nCoV; coronavirus disease 2019; COVID-19; acute respiratory disease; case definition; epidemiology; Australia

The following epidemiological data are subject to change both domestically and internationally due to the rapidly evolving situation. Australian cases are still under active investigation. While every effort has been made to standardise the investigation of cases nationally, there may be some differences between jurisdictions.

In Australia:

- Seventy-one COVID-19 cases, including two deaths, were notified up until 19:00 AEDT 7 March 2020;
  - Sixteen cases had direct or indirect links to mainland China;
  - Ten cases, including one death, were among the ‘Diamond Princess’ cruise ship passengers repatriated from Japan;
  - Sixteen cases had direct or indirect links to the Islamic Republic of Iran;
  - Fourteen had a recent travel history to other countries;
  - Fifteen cases, including one death, had no recent history of overseas travel;
- On 4 March 2020, the Australian Health Protection Principal Committee (AHPPC) recommended that the current travel restrictions for mainland China and the Islamic Republic of Iran remain in place for a further seven days; and
- On 5 March 2020, travel restrictions were announced for travellers from Republic of Korea and enhanced health screening for travellers from Italy.
Internationally:

- 101,927 infections have been confirmed globally, with 3,486 deaths;
- The majority of confirmed infections (79%; n = 80,651) and deaths (88%; n = 3,070) have been reported in mainland China;
- Outside of mainland China, cases (n = 21,276) have been reported in 96 countries, territories and areas, with approximately 78% of those cases reported from three countries: Italy, the Islamic Republic of Iran and Republic of Korea; and
- Outside of mainland China, 416 deaths were reported by 16 countries, territories and areas.

Domestic cases

There were 71 confirmed cases, including two deaths, reported in Australia as at 19:00 AEDT 7 March 2020 (Table 1). Of the 71 confirmed cases, 10 (14%) were among the ‘Diamond Princess’ cruise ship passengers repatriated from Japan (n = 164) to the Northern Territory on 20 February 2020. The remaining cases were reported in New South Wales (n = 33), Victoria (n = 8), Queensland (n = 12), Western Australia (n = 1), South Australia (n = 6) and Tasmania (n = 1) (Figure 1).

Of the 71 confirmed cases, 16 (23%) had direct or indirect links to mainland China, 10 (14%) were associated with the ‘Diamond Princess’ cruise ship, 16 (23%) had direct or indirect links to the Islamic Republic of Iran, 14 (20%) had a recent travel history to other countries and 15 (21%) had no recent history of overseas travel. Of the 15 cases who had no recent history of overseas travel, these were all reported in New South Wales. Twelve of the cases were associated with an aged care facility, including four residents, three staff members and several close contacts outside of the facility. A further two cases were associated with a workshop and the source of infection/exposure for the remaining case was under investigation at the time of writing. The identification of COVID-19 clusters in New South Wales with no recent history of overseas travel in any of the primary/index cases suggests that there has potentially been some very limited local transmission within New South Wales.

The median age of all 71 reported Australian cases was 45 years (range 0–94 years), with the highest proportion of cases aged 50–59 years (Table 2). Male-to-female ratio was approximately 1:1. Twenty-two cases have been reported to have cleared their infections, and two cases were reported to have died. Of the two cases that died, both were aged over 65 years.

Of the 71 confirmed cases, 34 (48%) had symptoms recorded. Cough was the most commonly reported symptom (Table 3) and no cases reported irritability/confusion, abdominal pain or acute respiratory disease.

International cases

As at 19:00 AEDT 7 March 2020, the number of confirmed COVID-19 cases reported to the World Health Organization (WHO) was 101,927 globally.1 The proportion of new cases reported from mainland China has continued to decrease, from 98% on 22 February 2020 to 79% (n = 80,651) on 7 March 2020.1,2 On 26 February 2020, the number of new cases outside of mainland China exceeded the number reported from mainland China for the first time and this trend has continued to date (Figure 2). The total number of confirmed COVID-19 cases reported by 96 countries, territories and areas outside of

mainland China in the current reporting week have increased almost four-fold (n = 21,276) compared to the preceding week (n = 5,447), where 696 confirmed cases were associated with the cruise ship 'Diamond Princess'. The Republic of Korea reported 33% (n = 6,767) of all cases outside of mainland China, Italy reported 23% (n = 4,636), the Islamic Republic of Iran 23% (n = 4,747) and Japan 2% (n = 408). Thirty-five new countries, territories and areas reported cases of COVID-19 in the past seven days. Of all the countries, territories and areas outside of mainland China with known transmission classification (n = 87), 45 (52%) have reported local transmission of COVID-19. Cambodia, Nepal and Sri Lanka have not reported any new cases for at least 14 days.

Globally, 3,486 deaths have been reported, with 85% (n = 2,959) reported from Hubei Province, China and 111 deaths reported from elsewhere within mainland China. The remaining 416 deaths were reported by 16 countries, territories and areas outside of mainland China.

- WHO declares the outbreak of COVID-19 a Public Health Emergency of International Concern
- WHO starts reporting both laboratory confirmed and clinically diagnosed cases from Hubei Province
- Hubei Province cease reporting clinically diagnosed cases
Country in focus: the Islamic Republic of Iran

Data on confirmed cases of COVID-19 in the Islamic Republic of Iran have not been made publicly available. The following is therefore a brief summary based on information obtained from WHO situation reports.

The Islamic Republic of Iran reported its first confirmed case of COVID-19 on 20 February 2020. From then, reported cases in the Islamic Republic of Iran increased rapidly, from two confirmed cases on 20 February 2020 to 4,747 on 7 March 2020. Among the cases reported as at 7 March 2020, 30% (n = 1,413) were reported in Tehran, 11% (n = 523) in Qom and 9% (n = 424) in Gilan. The Islamic Republic of Iran is one of the countries outside of mainland China with the most rapid growth of COVID-19 cases (Figure 3).

Based on confirmed cases up to 7 March 2020, the case fatality rate (CFR) for the Islamic Republic of Iran has been calculated at 2.6%. As the outbreak continues, the confirmed CFR may change. The current calculated CFR does not include the number of cases with mild infections that may be missed from current surveillance, nor does it account for the recently confirmed cases that may subsequently develop severe disease and die.

Background

On 31 December 2019, the World Health Organization (WHO) was notified about a large number of cases of pneumonia of unknown origin in Wuhan City, Hubei Province, China. Chinese authorities isolated and identified a novel coronavirus on 7 January 2020.5 WHO declared the outbreak of COVID-19 a Public Health Emergency of International Concern (PHEIC) on 30 January 2020.6

From 1 February 2020, Australia denied entry to anyone who had left or transited through mainland China, with the exception of Australian citizens, permanent residents and their immediate family and air crew who have been using appropriate personal protective equipment (Figure 4).7 The Australian Health Protection Principal Committee (AHPPC) have reviewed these restrictions weekly, and on 4 March 2020, they released a statement recommending current travel restrictions for mainland China and the Islamic Republic of Iran remain in place for a further seven days.8 On 5 March 2020, the Prime Minister announced new travel restrictions for travellers coming from Republic of Korea, and implementation of enhanced health screening for arrivals from Italy. From 5 March 2020, foreign nationals (excluding permanent residents of Australia) will be prevented from coming to Australia until 14 days after leaving Republic of Korea.9

The AHPPC acknowledged that Australia’s border measures may no longer be able to prevent the importation of COVID-19, and the primary focus should now be directed at domestic containment and preparedness.9 Local transmission of COVID-19 has occurred in Australia, highlighting the need of effective containment measures to limit spread. Early isolation of identified cases and quarantine of suspected cases and close contacts is a key measure to minimise transmission of COVID-19 in the community. However, as COVID-19 presents as mild illness in the majority of cases, early identification and isolation of cases may be difficult to achieve.

The current estimates on epidemiological parameters including severity, transmissibility and incubation period are uncertain. Estimates are likely to change as more information becomes available.
Figure 3: Number of COVID-19 cases by country and days since passing 100 cases, up to 7 March 2020

- Italy
- Islamic Republic of Iran

Total number of confirmed cases vs. Days since passing 100 cases.
Figure 4: A timeline of key events in the COVID-19 outbreak, Australia, up to 7 March 2020

- **31-Dec-19**: Cluster of pneumonia of unknown etiology in Wuhan, Hubei Province of China, reported to the WHO.
- **1-Feb-20**: Travel restrictions on foreign travellers coming from mainland China implemented.
- **3-Feb-20**: First assisted departure flight from Wuhan, China arrived on Christmas Island.
- **5-Feb-20**: Limited local transmission within a cluster first reported in Australia.
- **9-Feb-20**: Second assisted departure flight from Wuhan, China arrived in the Northern Territory.
- **17-Feb-20**: People from the first assisted departure flight returned to mainland Australia after completing quarantine.
- **20-Feb-20**: Passengers from 'Diamond Princess' repatriated from Japan to Northern Territory.
- **23-Feb-20**: People from the second assisted departure flight returned to home state after completing quarantine.
- **25-Jan-20**: First confirmed COVID-19 case reported in Australia.
- **5-Mar-20**: Passengers from 'Diamond Princess' returned to home state after completing quarantine. Travel restrictions on foreign travellers coming from Republic of Korea implemented.
- **1-Mar-20**: First COVID-19 death reported in Australia. Travel restrictions on foreign travellers coming from Islamic Republic of Iran implemented.
Severity

Ongoing evidence, including a recently published meta-analysis, supports previous research that COVID-19 presents as mild illness in the majority of cases with fever and cough being the most commonly reported symptoms. Severe or fatal outcomes tend to occur in the elderly or those with comorbid conditions. Examination of cases and their close contacts in China found an association between age and time from symptom onset to recovery. Median time to recovery was estimated to be 27 days in 20–29 year olds, 32 days in 50–59 year olds, and 36 days in those aged over 70 years. The study also found an association between clinical severity and time from symptom onset to recovery. Compared to people with mild disease, those with moderate and severe disease were associated with a 19% and 58% increase in recovery time, respectively.

Transmission

Human-to-human transmission of SARS-CoV-2 is via droplets and fomites from an infected person to a close contact. Examination of cases and their close contacts in China supports this. Household contacts and those who travelled with a confirmed COVID-19 case were strongly associated with an increased risk of infection. The study also examined the average time from symptom onset to disease confirmation and isolation among cases identified through symptom-based (i.e. symptomatic screening at airports, community fever monitoring and testing of hospital patients) and contact-based (i.e. monitoring and testing of close contacts of confirmed COVID-19 cases) surveillance. Compared to cases identified through symptom-based surveillance, cases identified through contact-based surveillance were associated with a 2.3 day decrease from symptom onset to disease confirmation, and a 1.9 day decrease from symptom onset to isolation. Based on modelling, researchers have found that effective contact tracing increases the probability of control.

Incubation period

No new research has been published on the incubation period for COVID-19. Please refer to COVID-19, Australia: Epidemiology Report 4 for the most recently published summary.

Treatment

Current clinical management of COVID-19 cases focuses on early recognition, isolation, appropriate infection control measures and provision of supportive care. Whilst there is no specific antiviral treatment currently recommended for patients with suspected or confirmed SARS-CoV-2 infection, multiple clinical trials are underway to evaluate a number of therapeutic agents, including remdesivir and lopinavir/ritonavir.

Virology

Based on modelling, researchers estimated that initial human SARS-CoV-2 infection was in November to early December 2019. An analysis based on 86 genomic sequences of SARS-CoV-2, obtained from the Global Initiative on Sharing All Influenza Data (GISAID), found many mutations. This suggests that SARS-CoV-2 has rapidly evolved since the outbreak occurred. Ongoing surveillance of sequences and shared mutations will assist with understanding of the global spread of the virus.

Comparison between COVID-19, SARS and MERS

Coronaviruses are a group of viruses that can cause upper respiratory tract infections in humans. Coronaviruses can occasionally cause severe diseases such as Middle East Respiratory Syndrome (MERS), Severe Acute Respiratory Syndrome (SARS) and more recently COVID-19. Similar to MERS and SARS, COVID-19 is thought to have originated from bats, and trans-
mitted to humans via an intermediate animal host. The intermediate animal host is currently unknown.\textsuperscript{18} Table 4 provides an overview of characteristics of COVID-19, MERS and SARS.

Public health response

The Report of the WHO-China Joint Mission on Coronavirus Disease 2019 (COVID-19) describes some of the key aspects associated with the evolving outbreak in mainland China, including the outbreaks transmission dynamics, disease progression and severity, mainland China's response and knowledge gaps. As part of the report, the following major recommendations were made for countries with imported cases and/or outbreaks of COVID-19:\textsuperscript{10}

1. Immediately activate the highest level of national Response Management protocols to ensure the all-of-government and all-of-society approach needed to contain COVID-19 with non-pharmaceutical public health measures;

2. Prioritise active, exhaustive case finding and immediate testing and isolation, painstaking contact tracing and rigorous quarantine of close contacts;

3. Fully educate the general public on the seriousness of COVID-19 and their role in preventing its spread;

4. Immediately expand surveillance to detect COVID-19 transmission chains, by testing all patients with atypical pneumonias, conducting screening in some patients with upper respiratory illnesses and/or recent COVID-19 exposure, and adding testing for the COVID-19 virus to existing surveillance systems (e.g. systems for influenza-like-illness); and

5. Conduct multi-sector scenario planning and simulations for the deployment of even more stringent measures to interrupt transmission chains as needed (e.g. the suspension of large-scale gatherings and the closure of schools and workplaces).

Methods

Data for this report were current as at 19:00 hours AEDT, 7 March 2020.

This report outlines what is known epidemiologically on COVID-19 in Australia and from publicly available data from WHO Situation Reports, other countries’ official updates and the scientific literature. Data on domestic cases in this report were collected from the National Notifiable Diseases Surveillance System (NNDSS) and jurisdictional health department media releases. The Communicable Diseases Network Australia (CDNA) developed the case definition for suspect and confirmed cases, which was modified at different time points during the outbreak (Table 5). Data was analysed using Stata to describe the epidemiology of COVID-19 in Australia and the progress of the epidemic.

Data for the international cases of COVID-19 by country were compiled from the latest WHO Situation Report. Case definitions may vary by country making comparisons difficult. Rapid reviews of the current state of knowledge on COVID-19 were conducted from the literature using PubMed.

Acknowledgements

This report represents surveillance data reported through CDNA as part of the nationally-coordinated response to COVID-19. We thank public health staff from incident emergency operations centres in state and territory health departments, and the Australian Government Department of Health, along with state and territory public health laboratories.

**Epidemiological criteria**
- Travel to (including transit through) a country considered to pose a risk of transmission in the 14 days before onset of illness.
- OR
- Close or casual contact in 14 days before illness onset with a confirmed case of COVID-19.

**Clinical criteria**
- Fever
- OR
- Acute respiratory infection (e.g., shortness of breath or cough) with or without fever.

B. If the patient has severe community-acquired pneumonia (critically ill) and no other cause is identified, with or without recent international travel, they are classified as a suspect case.

C. If the patient has moderate or severe community-acquired pneumonia (hospitalised) and is a healthcare worker, with or without international travel, they are classified as a suspect case.

\* Higher risk of transmission: mainland China, Iran (Islamic Republic of), Italy, Republic of Korea; moderate risk: Cambodia, Hong Kong SAR, Indonesia, Japan, Singapore and Thailand
