The Department of Health acknowledges the providers of the many sources of data used in this report and greatly appreciates their contribution.

**KEY MESSAGES**

It is important to note that due to the COVID-19 epidemic in Australia, data reported from the various influenza surveillance systems may not represent an accurate reflection of influenza activity. Results should be interpreted with caution, especially where comparisons are made to previous influenza seasons. Interpretation of 2020 influenza activity data should take into account, but are not limited to, the impact of social distancing measures, likely changes in health seeking behaviour of the community including access to alternative streams of acute respiratory infection specific health services, and focussed testing for COVID-19 response activities. Current COVID-19 related public health measures and the community's adherence to public health messages are also likely having an effect on transmission of acute respiratory infections, including influenza.

- **Activity** – Following a high start to the 2020 interseasonal period, currently, influenza and influenza-like illness (ILI) activity are lower than average across all systems for this time of year. At the national level, notifications of laboratory-confirmed influenza have substantially decreased since mid-March and remain low.
- **Impact** – Given low case numbers of laboratory-confirmed notifications for influenza, it is likely that there is minimal impact on society due to influenza circulation in the 2020 season.
- **Severity** – There is no indication of the potential severity of the 2020 season at this time. In the year to date, of the 21,187 notifications of laboratory confirmed influenza, 36 (0.17%) laboratory-confirmed influenza-associated deaths have been notified to the National Notifiable Diseases Surveillance System (NNDSS).
- **Virology** – In the year to date, the majority of nationally reported laboratory-confirmed influenza cases were influenza A (87.1%).
- **Vaccine match and effectiveness** – Given low case numbers of influenza in 2020, it is currently difficult to assess vaccine match and effectiveness.

**Introduction**

Each year, the influenza virus changes and different strains can circulate in the population. Particular subtypes of influenza can affect different groups of the population more than others. Depending on the susceptibility of the population, the subtypes that are circulating and the changes to the virus itself, the influenza season can be very different year to year. Our surveillance systems help us to understand influenza activity, severity of the infection in individuals and impact of the illness on society in Australia. We are also able to monitor which influenza viruses are circulating, which populations might be more affected, the effectiveness of the vaccine, and any resistance to antiviral drugs that has developed.

**Activity** measures the capacity of the circulating influenza viruses to spread person to person and may be measured indirectly through systems that monitor ILI and more directly through systems that monitor laboratory-confirmed influenza.

**Impact** measures how the influenza epidemic affects society, including stress on health-care resources and societal and economic consequences.

**Severity** is a measure of adverse outcomes or complications as a result of ILI such as hospital referrals, admissions, need for intensive care and deaths. Measuring and understanding the severity of circulating influenza is difficult to establish at the beginning, or during a low, influenza season. The proportion of confirmed influenza cases with serious outcomes might be skewed initially because there are only a small number of people notified. This means that the measure of severity will vary substantially fortnight to fortnight until numbers are sufficiently high and there is enough data for measurements to stabilise. An assessment of severity can be provided once the signals become clearer.
Analysis of influenza surveillance systems

Healthdirect

Healthdirect provides free health triage advice and information services by telephone and online, and can assist in identifying symptoms including those that may be classified as an ILI syndrome. Community level ILI syndromic trends are monitored using Healthdirect data.

Activity

- Calls to Healthdirect relating to ILI in the year to date appear to have been impacted by bushfires and COVID-19 (Figure 1).
- In late January and early February 2020, the Healthdirect helpline reported an increase in ILI calls related to bushfire smoke.
- During February and March, there was an increase in media coverage of COVID-19 and its symptoms, which overlap with ILI symptoms reported.
- The National Coronavirus Helpline was established on 16 March 2020. Since then, callers to the Healthdirect helpline who have concerns about COVID-19 have been diverted to the National Coronavirus Helpline. This explains the sudden drop in ILI related calls to the helpline in mid-March.
- This fortnight (21 September to 04 October 2020), 3.3% of calls to the Healthdirect helpline have been related to ILI, a slight increase from 3.0% in the previous fortnight.

Figure 1. Per cent of calls to Healthdirect related to ILI, Australia, 01 January 2015 to 04 October 2020, by month and week of call*

![Graph showing per cent of calls to Healthdirect related to ILI, Australia, 01 January 2015 to 04 October 2020, by month and week of call.](source: Healthdirect)

* All data are preliminary and subject to change as updates are received.

Flutracking

Flutracking is an online syndromic surveillance system which monitors ILI in the community.

Activity

- Flutracking began reporting earlier than usual this year due to COVID-19. As such, historical comparisons are not available for data reported prior to April 2020.
- Since reporting commenced in week 8, Flutracking participants reporting ILI (fever and cough) has decreased from a peak of 1.5% to a low of 0.2% from weeks 17 to 20 (Figure 2).
- This fortnight (21 September to 04 October 2020), Flutracking participants reporting ILI (0.27%) was the same as the previous fortnight (0.27%).
Impact

- Since week 8, the proportion of Flutracking survey respondents reporting having ILI and taking time off regular duties while unwell has declined from a peak of 1.1% in week 8 to a low of 0.09% in week 19. From week 20 to week 24 this proportion increased and remained relatively unchanged through to week 40.
- This fortnight (21 September to 04 October 2020), Flutracking participants reporting ILI and taking time off regular duties (0.17%) is similar to the previous fortnight (0.18%).

Figure 2. Proportion of fever and cough among Flutracking participants, Australia, between February and October, 2015 to 2020, by month and week*

* All data are preliminary and subject to change as updates are received.

Sentinel General Practitioners (ASPREN)

ASPREN is a year-round sentinel general practice surveillance system in which general and nurse practitioners report de-identified information on the number of ILI patient presentations seen in participating practices each week.

It should be noted that in addition to the overarching impacts of COVID-19 on influenza surveillance systems (see page 1), interpretation of ASPREN’s 2020 influenza data should take into account the following COVID-19 impacts:

- changes in the health seeking behaviour at ASPREN sentinel sites due to the availability of telehealth and respiratory clinics may result in less presentations to General Practice (GP); and
- changes to GPs swabbing at ASPREN sentinel sites, due to the availability of telehealth and respiratory clinics, may result in a lower number of swabs being undertaken by ASPREN reporters.

Activity

- From weeks 1 to 9, sentinel ASPREN GPs reported an average of 1.7 per 1,000 consultations per week due to ILI.
- From week 9, ILI consultations increased and peaked in week 12 (5.4 per 1,000), following which they have declined (Figure 3).
- This fortnight (21 September to 04 October 2020), 0.5 per 1,000 consultations due to ILI were reported by sentinel ASPREN GPs.
- In the year to date, the proportion of ILI cases with confirmed influenza seen by sentinel GPs is low. Of the 746 ILI cases presenting to sentinel GPs who were tested for influenza, 21 (2.8%) were influenza positive.
- This fortnight (21 September to 04 October 2020), there were no influenza positive results among patients that were tested through sentinel ASPREN GPs.
**Virology**

- Of the 21 influenza positive samples detected year to date, 19 were influenza A (14 influenza A(H1N1)pdm09, three influenza A(H3N2) and two influenza A(unsubtyped)) and two were influenza B (one influenza B/Victoria and one influenza B (unsubtyped)) (Figure 4).
- The most common respiratory virus reported so far this year of cases reported from sentinel ASPREN GPs is rhinovirus, accounting for 31.8% (237/746) of all tests.

**Figure 4. Proportion of respiratory viral tests positive for influenza in ASPREN ILI patients and ASPREN ILI consultation rate, Australia, 01 January to 04 October 2020, by month and week**

* All data are preliminary and subject to change as updates are received.
Sentinel Laboratories

Sentinel laboratory surveillance systems provide fortnightly reporting of influenza testing. This includes the number of tests undertaken, the number of positive results, and the detected viruses.

Activity

- Of the 453,011 samples tested across sentinel laboratories in the year to date, 1,995 (0.44%) were positive for influenza.
- Detections of influenza across sentinel laboratories increased from 4.5% in week 1 to 8.3% in week 4 (unweighted percentage of tests positive for influenza across all sentinel laboratories) and have steadily decreased to at or below 0.1% from week 15 (Figure 5).

Figure 5. Proportion of sentinel laboratory tests positive for influenza, 01 January to 04 October 2020, by contributing laboratory or jurisdiction and month and week

Virology

- In the year to date, 0.44% of samples detected in sentinel laboratories were positive for influenza. Of these 81.7% were influenza A (of which 34.7% were influenza A(unsubtyped), 18.0% were influenza A(H1N1)pdm09, 3.7% were influenza A(H3N2)), and 18.3% were influenza B (Figure 6).
- This fortnight (21 September to 04 October 2020), there was one positive influenza A sample detected in sentinel laboratories.
- This fortnight (21 September to 04 October 2020), the most commonly detected respiratory viruses by laboratory site were:
  - Rhinovirus in both weeks by the Institute of Clinical Pathology and Medical Research in New South Wales (NSW), South Australia (SA), and Tasmania (TAS);
  - Picornavirus and Adenovirus in week 39 by Victorian Infectious Diseases Reference Laboratory (VIDRL), where there was no viral detection in week 40 by VIDRL; and
  - COVID-19 in week 39 and Respiratory syncytial virus (RSV) in week 40 in Western Australia (WA).
Figure 6. Proportion of sentinel laboratory tests positive for influenza and total number of specimens tested, 01 January to 04 October 2020, by subtype and month and week*

* Total number of tests include all specimens that were tested for influenza, including multiplex respiratory panels which include both influenza and SARS-CoV2. Testing methodologies in the response to COVID-19 vary across jurisdictions.

All data are preliminary and subject to change as updates are received.

The Influenza Complications Alert Network (FluCAN)

*FluCAN conducts surveillance of severe influenza at sentinel hospitals across the country during the influenza season.*

**Activity**

- Since seasonal sentinel hospital surveillance began on 16 March 2020, the total number of people admitted to hospital with confirmed influenza (n=14) has been below historical trends (Figure 7).
- This fortnight (21 September to 04 October 2020), there were no confirmed influenza cases admitted to a participating FluCAN hospital. The last reported case admitted to a participating FluCAN hospital was in week 33.

**Severity**

- Of the 14 people with confirmed influenza admitted to sentinel hospitals since 16 March 2020, only one has been admitted to an intensive care unit (ICU).

**Virology**

- Of the 14 confirmed influenza admissions to sentinel hospitals:
  - ten were influenza A (four influenza A(H1N1)pdm09, five unsubtyped and one A(H3N2)); and
  - four were influenza B (Figure 8).

**At-risk Populations**

- Of the 14 people admitted with confirmed influenza:
  - eight were children aged 15 years and younger, of which one was admitted to ICU;
  - three were aged between 16 and 64 years; and
  - three were aged 65 years and older.
Figure 7. Number of influenza hospitalisations at sentinel hospitals, between March and October, 2015 to 2020 by month and week*

* All data are preliminary and subject to change as updates are received.

Figure 8. Number of influenza hospitalisations at sentinel hospitals by subtype and ICU admission, 16 March to 04 October 2020, by month and week*

* All data are preliminary and subject to change as updates are received.
National Notifiable Diseases Surveillance System (NNDSS) Notifications

The NNDSS coordinates the national surveillance of more than 60 communicable diseases or disease groups. Notifications of laboratory-confirmed influenza are made to the States or Territory health authority and supplied daily to the Australian Government Department of Health via the NNDSS for collation, analysis and to assist in the coordination of public health responses.

Activity

- In the year to date, there have been 21,187 notifications of laboratory-confirmed influenza to the NNDSS.
- This fortnight (21 September to 04 October 2020), there were 19 notifications.
- There was a steady increase in notifications from weeks 1 to 11 of 2020. From week 12, notifications have declined and remained low (Figure 9).

Figure 9. Notifications of laboratory confirmed influenza, Australia, 01 January 2015 to 04 October 2020, by month and week of diagnosis*

Geographical distribution of activity

- Notifications of influenza have declined across all jurisdictions and remain low compared to previous weeks (Figure 10).
- In the year to date, of the 21,187 notifications of influenza reported to the NNDSS, there have been:
  - 7,200 notifications in New South Wales (NSW);
  - 6,001 notifications in Queensland (QLD);
  - 4,636 notifications in Victoria (VIC);
  - 1,525 notifications in South Australia (SA);
  - 1,189 notifications in Western Australia (WA);
  - 280 notifications in the Northern Territory (NT);
  - 194 notifications in the Australian Capital Territory (ACT); and
  - 162 notifications in Tasmania (TAS).

* NNDSS notification data provided for the current and most recent weeks may be incomplete. All data are preliminary and subject to change as updates are received.

Source: NNDSS

*NNDSS notification data provided for the current and most recent weeks may be incomplete. All data are preliminary and subject to change as updates are received.

For further information regarding influenza activity at the jurisdictional level, please refer to the following State and Territory health surveillance reports:

Severity

- So far in 2020, of the 21,187 notifications of laboratory confirmed influenza, 36 (0.17%) laboratory-confirmed influenza-associated deaths have been notified to the NNDSS.
- Where subtyping information was available, seven deaths were associated with influenza A(H1N1), one with influenza A(H3N2), and two with influenza B.
- Of the notified deaths, one was in a child aged younger than 5 years, seven were aged between 20 and 64 years, and 28 were aged 65 years and older.
- The median age of notified deaths was 79 years.

Note that the number of influenza-associated deaths reported to the NNDSS does not represent the true mortality associated with this disease. The number of deaths is reliant on the follow up of cases to determine
the outcome of their infection. The follow up of cases is not a requirement of notification, and are only inclusive of laboratory-confirmed cases of influenza. Due to retrospective revision, the variation across jurisdictions in methodology, representativeness and timeliness of death data, and reporting of an outcome of infection not being a requirement of notification, year on year comparisons of deaths in notified cases of influenza may not be reliable.

Virology

- In the year to date, 87.1% of notifications of laboratory-confirmed influenza to the NNDSS were influenza A (of which, 91.2% were influenza A(unsubtyped), 7.7% were influenza A(H1N1)pdm09 and 1.1% were influenza A(H3N2)), 12.6% were influenza B, and less than 1% were influenza A&B co-infections or untyped (Figure 11).
- This fortnight (21 September to 04 October 2020), of the 19 notifications of laboratory-confirmed influenza reported to the NNDSS, 68.4% (n=13) were influenza A (of which all (100%) were A(unsubtyped)), and 31.6% (n=6) were influenza B. There were zero influenza A&B co-infections, and zero untyped notifications.
- In the year to date, the proportion of all notifications reported as influenza A has been fairly similar across jurisdictions, ranging from 86.6% in ACT to 90.4% in NT, with the exception of SA (79.3%). The proportion of all notifications reported as influenza B has increased since week 37 (Figure 12).

At-risk Populations

- In the year to date, notification rates have been highest in children aged less than 10 years (115.4 notifications per 100,000), while rates in adults aged 65 years or older (73.2 notifications per 100,000) have been low (Figure 13).
- In the year to date, influenza A accounted for the greatest number of notifications across all age groups.
- Where further subtyping information was available, in the year to date, notifications were highest in:
  - adults aged 80 years and over (7.9 per 100,000) and children aged less than five years (7.3 per 100,000) for influenza A(H1N1)pdm09;
  - adults aged 85 years and older (2.5 per 100,000) for influenza A(H3N2); and
  - children aged 5 to 9 years (19.3 per 100,000) for influenza B.

The WHOCC monitors the frequent changes in influenza viruses with the aim of reducing the impact of influenza through the use of vaccine containing currently circulating strains.

Australian Influenza Vaccines Composition 2020

In 2020 all seasonal influenza vaccinations registered for use in Australia are quadrivalent influenza vaccines (QIVs). The influenza virus strains included in the 2020 seasonal influenza vaccines in Australia are:

- A/Brisbane/02/2018 (H1N1)pdm09-like virus;
- A/South Australia/34/2019 (H3N2)-like virus;
- B/Washington/02/2019-like (B/Victoria lineage) virus; and
- B/Phuket/3073/2013-like (B/Yamagata lineage) virus.

The best way to determine how well the vaccine protects against circulating viruses during the season is by determining the vaccine effectiveness. These estimates provide an indication of how effective the vaccine was in providing protection against influenza infection. Vaccine effectiveness is usually estimated from observational studies and is calculated after the end of the influenza season, though interim analyses are sometimes available where there is sufficient data.

Virology

- From 01 January to 06 October 2020, the WHOCC characterised 306 influenza viruses (Table 1). Of these, 91.5% were influenza A (of which, 87.9% were A(H1N1)pdm09 and 12.1% A(H3N2)), 8.2% were influenza B/Victoria lineage, and 0.3% were influenza B/Yamagata lineage.

Vaccine match

- Of the 306 isolates characterised for similarity to their corresponding vaccine components by haemagglutination inhibition (HI) assay (Table 1):
  - 44% of influenza A(H1N1)pdm09 isolates were antigenically similar to the corresponding vaccine components and 56% were characterised as low reactors;
  - 65% of influenza A(H3N2) isolates were antigenically similar to the corresponding vaccine components and 35% were characterised as low reactors;
  - Of the 25 influenza B/Victoria isolates, all were antigenically similar to the corresponding vaccine component; and
  - The one influenza B/Yamagata isolate characterised year to date was antigenically similar to the corresponding vaccine component.

* Viruses tested by the WHO CC are not necessarily a random sample of all those in the community. State indicates the residential location for the individual tested, not the submitting laboratory. There may be up to a month delay on reporting of samples.

Antiviral Resistance

- The WHOCC reported that from 01 January to 06 October 2020, two of the 323 influenza viruses tested for neuraminidase inhibitor resistance, demonstrated reduced inhibition to Oseltamivir.
Data considerations

This report presents an overview of influenza activity based on a number of complimentary systems. No one single system, including notification data, provides the full picture on influenza, because influenza is a common disease and its presenting symptoms are non-specific. The epidemiology of influenza is informed by a number of different systems based in the community, laboratories, primary care and hospitals, as well as notifiable diseases data, which includes officially reported deaths. The information in this report is reliant on the surveillance sources available to the Department of Health at the time of production.

Data in this summary is reported by International Organization for Standardization (ISO) 8601 weeks, with the week ending on Sunday. Throughout the summary, where the year to date is presented, this includes data from 1 January to 04 October 2020. NNDSS data were extracted on 07 October 2020. Due to the dynamic nature of the NNDSS and other surveillance systems, data in this report are subject to retrospective revision and may vary from data reported in other national reports and reports by states and territories. Detailed notes on interpreting the data presented in this report are available at the Department of Health’s Australian Influenza Surveillance Report website (www.health.gov.au/flureport).

While every care has been taken in preparing this report, the Commonwealth does not accept liability for any injury or loss or damage arising from the use of, or reliance upon, the content of the report. Delays in the reporting of data may cause data to change retrospectively. For further details about information contained in this report please contact the Influenza Surveillance Team (flu@health.gov.au).
